

# GridWorld Case Study

## Part 5: Grid Data Structures (AP<sup>®</sup> CS AB only)

### The AbstractGrid Class

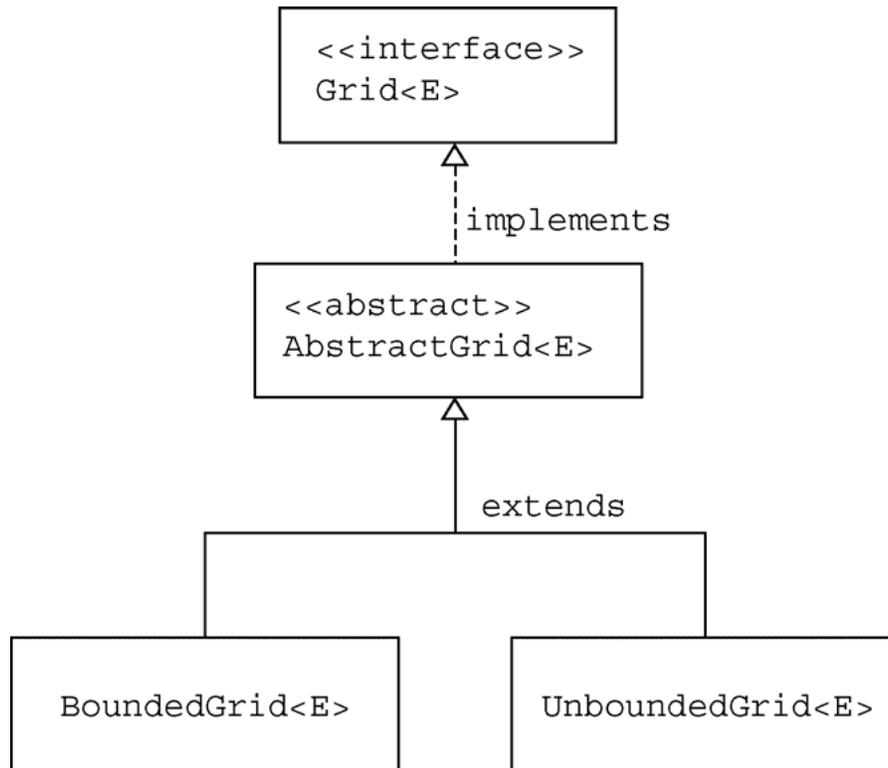

Two concrete implementations of the `Grid` interface are provided, one for a bounded grid that has a fixed number of rows and columns, and a second for an unbounded grid, for which any row and column values are valid. Rather than have repeated code in two classes, the `AbstractGrid` class defines five methods of the `Grid` interface that are common to both implementations.

```
public ArrayList<E> getNeighbors(Location loc)
public ArrayList<Location> getValidAdjacentLocations(Location loc)
public ArrayList<Location> getEmptyAdjacentLocations(Location loc)
public ArrayList<Location> getOccupiedAdjacentLocations(Location loc)
public String toString()
```

The code for these methods uses other methods specified in the interface. Here is the definition of the `getNeighbors` method. Note that the same method works for bounded and unbounded grids.

```
public ArrayList<E> getNeighbors(Location loc)
{
    ArrayList<E> neighbors = new ArrayList<E>();
    for (Location neighborLoc : getOccupiedAdjacentLocations(loc))
        neighbors.add(get(neighborLoc));
    return neighbors;
}
```

The `AbstractGrid` class is a superclass of the `BoundedGrid` and `UnboundedGrid` classes. Since `AbstractGrid` does not define all methods specified by the `Grid` interface, it is an abstract class. The concrete `BoundedGrid` and `UnboundedGrid` classes define the methods of the `Grid` interface that are not defined in `AbstractGrid`. This design is illustrated in the following figure.

### Do You Know?

#### Set 10

The source code for the `AbstractGrid` class is in Appendix D.

1. Where is the `isValid` method specified? Which classes provide an implementation of this method?
2. Which `AbstractGrid` methods call the `isValid` method? Why don't the other methods need to call it?
3. Which methods of the `Grid` interface are called in the `getNeighbors` method? Which classes provide implementations of these methods?
4. Why must the `get` method, which returns an object of type `E`, be used in the `getEmptyAdjacentLocations` method when this method returns locations, not objects of type `E`?
5. What would be the effect of replacing the constant `Location.HALF_RIGHT` with `Location.RIGHT` in the two places where it occurs in the `getValidAdjacentLocations` method?

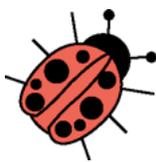

## The BoundedGrid Class

A bounded grid has a fixed number of rows and columns. You can access only locations that are within the bounds of the grid. If you try to access an invalid location, a run-time exception will be thrown.

The `BoundedGrid<E>` class stores grid occupants in a two-dimensional array.

```
private Object[] [] occupantArray;
```

Note that `occupantArray` is declared to hold references of type `Object` rather than the generic type `E`. (In the Java language, it is impossible to declare arrays of generic types.) Nevertheless, all elements of `occupantArray` must belong to the type `E`. Only the `put` method adds elements to the array, and it requires elements of type `E`.

### Do You Know?

#### Set 11

The source code for the `BoundedGrid` class is in Appendix D.

1. What ensures that a grid has at least one valid location?
2. How is the number of columns in the grid determined by the `getNumCols` method? What assumption about the grid makes this possible?
3. What are the requirements for a `Location` to be valid in a `BoundedGrid`?

In the next four questions, let  $r$  = number of rows,  $c$  = number of columns, and  $n$  = number of occupied locations.

4. What type is returned by the `getOccupiedLocations` method? What is the time complexity (Big-Oh) for this method?
5. What type is returned by the `get` method? What parameter is needed? What is the time complexity (Big-Oh) for this method?
6. What conditions may cause an exception to be thrown by the `put` method? What is the time complexity (Big-Oh) for this method?

7. What type is returned by the `remove` method? What happens when an attempt is made to remove an item from an empty location? What is the time complexity (Big-Oh) for this method?
8. Based on the answers to questions 4, 5, 6, and 7, would you consider this an efficient implementation? Justify your answer.

## The `UnboundedGrid` Class

In an unbounded grid, any location is valid, even when the row or column is negative or very large. Since there is no bound on the row or column of a location in this grid, the `UnboundedGrid<E>` class does not use a fixed size two-dimensional array. Instead, it stores occupants in a `Map<Location, E>`. The key type of the map is `Location` and the value type is `E`, the type of the grid occupants.

The `numRows` and `numCols` methods both return `-1` to indicate that an unbounded grid does not have any specific number of rows or columns. The `isValid` method always returns `true`. The `get`, `put`, and `remove` methods simply invoke the corresponding `Map` methods. The `getOccupiedLocations` method returns the same locations that are contained in the key set for the map.

### Do You Know?

#### Set 12

The source code for the `UnboundedGrid` class is in Appendix D.

1. Which method must the `Location` class implement so that an instance of `HashMap` can be used for the map? What would be required of the `Location` class if a `TreeMap` were used instead? Does `Location` satisfy these requirements?
2. Why are the checks for `null` included in the `get`, `put`, and `remove` methods? Why are no such checks included in the corresponding methods for the `BoundedGrid`?
3. What is the average time complexity (Big-Oh) for the three methods: `get`, `put`, and `remove`? What would it be if a `TreeMap` were used instead of a `HashMap`?
4. How would the behavior of this class differ, aside from time complexity, if a `TreeMap` were used instead of a `HashMap`?
5. Could a map implementation be used for a bounded grid? What advantage, if any, would the two-dimensional array implementation that is used by the `BoundedGrid` class have over a map implementation?

## Exercises

1. Suppose that a program requires a very large bounded grid that contains very few objects and that the program frequently calls the `getOccupiedLocations` method (as, for example, `ActorWorld`). Create a class `SparseBoundedGrid` that uses a “sparse array” implementation. Your solution need not be a generic class; you may simply store occupants of type `Object`.

The “sparse array” is an array list of linked lists. Each linked list entry holds both a grid occupant and a column index. Each entry in the array list is a linked list or is `null` if that row is empty.

You may choose to implement the linked list in one of two ways. You can use raw list nodes.

```
public class SparseGridNode
{
    private Object occupant;
    private int col;
    private SparseGridNode next;
    . . .
}
```

Or you can use a `LinkedList<OccupantInCol>` with a helper class.

```
public class OccupantInCol
{
    private Object occupant;
    private int col;
    . . .
}
```

For a grid with  $r$  rows and  $c$  columns, the sparse array has length  $r$ . Each of the linked lists has maximum length  $c$ .

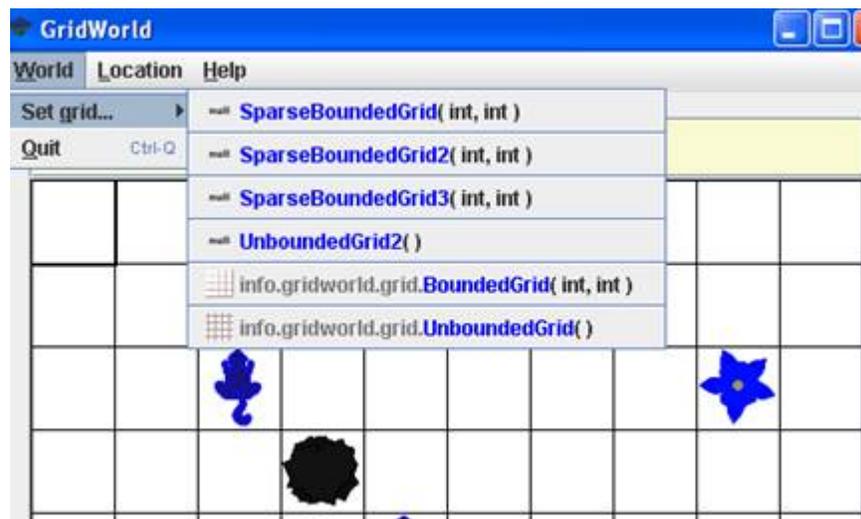

Implement the methods specified by the `Grid` interface using this data structure. Why is this a more time-efficient implementation than `BoundedGrid`?

The World has a public `addGridClass` method. Since the `ActorWorld` is a `World`, you can call this method in a runner. Here is the code to add a new grid to the GUI.

```
import info.gridworld.actor.Actor;
import info.gridworld.actor.ActorWorld;
import info.gridworld.grid.Location;
import info.gridworld.actor.Critter;
import info.gridworld.actor.Rock;
import info.gridworld.actor.Flower;

/**
 * This class runs a world with additional grid choices.
 */
public class SparseGridRunner
{
    public static void main(String[] args)
    {
        ActorWorld world = new ActorWorld();
        world.addGridClass("SparseBoundedGrid");
        world.addGridClass("SparseBoundedGrid2");
        world.addGridClass("SparseBoundedGrid3");
        world.addGridClass("UnboundedGrid2");
        world.add(new Location(2, 2), new Critter());
        world.show();
    }
}
```

When you execute a runner class and choose the World menu->set grid, the new grid type will be available for you to choose.

2. Consider using a `HashMap` or `TreeMap` to implement the `SparseBoundedGrid`. How could you use the `UnboundedGrid` class to accomplish this task? Which methods of `UnboundedGrid` could be used without change?

Fill in the following chart to compare the expected Big-Oh efficiencies for each implementation of the `SparseBoundedGrid`.

Let  $r$  = number of rows,  $c$  = number of columns, and  $n$  = number of occupied locations

Methods	<code>SparseGridNode</code> version	<code>LinkedList&lt;OccupantInCol&gt;</code> version	<code>HashMap</code> version	<code>TreeMap</code> version
<code>getNeighbors</code>				
<code>getEmptyAdjacentLocations</code>				
<code>getOccupiedAdjacentLocations</code>				
<code>getOccupiedLocations</code>				
<code>get</code>				
<code>put</code>				
<code>remove</code>				

3. Consider an implementation of an unbounded grid in which all valid locations have non-negative row and column values. The constructor allocates a 16 x 16 array. When a call is made to the `put` method with a row or column index that is outside the current array bounds, double both array bounds until they are large enough, construct a new square array with those bounds, and place the existing occupants into the new array.

Implement the methods specified by the `Grid` interface using this data structure. What is the Big-Oh efficiency of the `get` method? What is the efficiency of the `put` method when the row and column index values are within the current array bounds? What is the efficiency when the array needs to be resized?
